Abstract

This study sheds light on how journalists respond to evolving debates within academia around topics including research integrity, improper use of metrics to measure research quality and impact, and the risks and benefits of the open science movement. Drawing on semi-structured interviews with 19 health and science journalists, we describe journalists' awareness of these controversies and the ways in which that awareness, in turn, shapes the practices they use to select, verify, and communicate research. Our findings suggest that journalists' perceptions of debates in scholarly communication vary widely, with some displaying a highly critical and nuanced understanding and others presenting a more limited awareness. Those with a more in-depth understanding report closely scrutinizing the research they report, carefully vetting the study design, methodology, and analyses. Those with a more limited awareness are more trusting of the peer review system as a quality control system and more willing to rely on researchers when determining what research to report on and how to vet and frame it. We discuss the benefits and risks of these varied perceptions and practices, highlighting the implications for the nature of the research media coverage that reaches the public.

Keywords: scholarly communication, science journalism, research integrity, open science; research assessment

17 **From impact metrics and open science to communicating research:**

18 **Journalists' awareness of academic controversies**

19 The systems of scholarly communication and journalism are deeply intertwined, with changes in
20 one influencing the values, norms, and practices of the other [e.g., 1,2]. Yet, the mechanisms
21 underpinning these interconnections are not well understood, with a lack of evidence into how
22 journalists make sense of, and adapt their work in response to, changes in scholarly communication [3].
23 To help fill this gap, we present a qualitative analysis of 19 interviews with health and science
24 journalists examining their perceptions of key scholarly communication debates (e.g., on “impact”
25 metrics, research integrity, open access [OA]) and how these perceptions, in turn, relate to the
26 professional norms, practices, and criteria they use to select, verify, and communicate research. In doing
27 so, we shed light on the consequences of the increasingly close coupling between science and journalism
28 [4,5] for scientists, journalists, and the public.

29 **Close relationships and heavy reliance between science and the media**

30 Decades of research have demonstrated the close and codependent relationships that can develop
31 between science journalists and the researchers whose work they report on [5,6]. These studies show that
32 science journalists rely heavily on interviews with researchers to help them identify new story ideas, vet
33 the quality of studies, contextualize and translate the findings for public audiences, frame the
34 implications, and more [7]. Journalists sometimes also rely on researchers for access to research papers
35 that are behind paywalls [8,9]. Researchers, in turn, rely on journalists to share new findings to the
36 public, gain societal legitimacy, and win funding—a reliance that may be increasing as scientists and
37 scientific institutions face growing pressures to demonstrate a wider societal “impact” of their work
38 [10,11].

39 Journalism and academia share many commonalities—including a shared commitment to
40 independent, rigorous investigation in pursuit of “truth”—but they are also distinct in important ways,

41 including differing epistemologies, ethical frameworks, and standards of practice (Bartleman et al.,
42 2024). As such, although the close relationships between journalists and scientists may enable them to
43 work together more efficiently [12], they also come with risks. In particular, scientists may prioritize the
44 norms, values, ethics, and practices—or *logics*—of journalism over those of science, potentially
45 resulting in a loss of scientific autonomy with respect to how research is conducted [13] and
46 communicated [11,14,15]. For journalists, internalizing the logics of science may result in media
47 coverage that prioritizes the interests and perspectives of researchers over those of the public. Moreover,
48 journalists’ heavy reliance on scientists could prevent them from reporting what is relevant to society
49 (i.e., rather than what is relevant for particular scientists or scientific institutions). It could also
50 compromise their ability to provide a balanced portrait of reality that gives space for competing
51 interpretations or dissenting perspectives or act as watchdogs of the powerful (e.g., scientists, funders,
52 pharmaceutical companies) [16].

53 Understanding the potential risks and benefits of journalists’ proximity to scientists is especially
54 important given growing concerns about research integrity, efforts at research assessment reform away
55 from the use of “impact” metrics, and broader changes in scholarly communication resulting from the
56 open science (OS) movement [17]. For instance, a nuanced understanding of problematic aspects of
57 science (e.g., research fraud, retractions, improper use of metrics) is essential if journalists are to
58 effectively perform their watchdog role—i.e., to sound an alarm when the actions of scientists put the
59 public interest at risk. Yet, a more incomplete understanding of these issues could result in media
60 coverage that inaccurately portrays research infractions of evidence that science is “broken,” damaging
61 public trust [18,19]. Similarly, journalists’ awareness of OS practices—such as the use of preprints, OA
62 papers, or open data sets—may facilitate their work by enabling them to use research knowledge that
63 would otherwise be inaccessible [20–22]. Yet, a more superficial understanding of these practices, or
64 one that prioritizes the interests of science over those of the public, could result in problematic media

65 coverage, such as stories conflating the OA movement with predatory publishing [23,24] or stories that
66 present preprints as if they were peer reviewed research [25–27].

67 Despite these potential risks and benefits, we lack research that has examined the *scientization* of
68 journalism—that is, “the influence that researchers exert on the media as they vie for their research (or
69 opinions) to be featured in lieu of other coverage” [3]. This exploratory study contributes to filling this
70 gap by documenting journalists’ awareness of key controversies within academia, and how this
71 understanding, in turn, shapes their practices for reporting on science.

72 **Evolving debates within scholarly communication**

73 In recent years, changes in the scholarly communication ecosystem have sparked debates about
74 interrelated concerns regarding research integrity, challenges of assessing research quality, and adverse
75 effects of impact metrics, as well as on the potential role of OS to either address or exacerbate these
76 concerns. These concerns, and the debates around them, are complex, involving actors at every level of
77 scientific systems, especially researchers and administrators at academic institutions.

78 Underscoring them all is a “publish-or-perish” culture that exerts pressure on academics to
79 produce as many research articles as possible and ensure they are published in prestigious and “high
80 impact” journals [28,29]. This pressure has led to a hyper-competitive academic environment that relies
81 heavily on mechanisms for tracking and assessing research and researchers for resource allocation (e.g.,
82 career progression, departmental funding, etc.) [30]. The effects of these practices are system-wide and
83 form part of a larger set of changes that some have described as the neoliberalization of the university
84 [31,32]. Addressing the full scope of these discussions and concerns is beyond the scope of this
85 literature review, but we touch on the more direct concerns in the following paragraphs, as they pertain
86 to how scholars understand and talk about their work with each other and, potentially, with the
87 journalists they engage with.

88 On a pragmatic level, the growing pressures to publish have fueled multiple concerns about
89 research integrity. Early among these was the so-called “replication crisis” stemming from the high
90 volume of studies whose findings could not be verified, either due to lack of methodological detail or
91 accessible data or because results were not robust enough [33]. More recently, the rise of a pay-to-
92 publish model fueled the rise of so-called “predatory journals” that charge authors but do not offer a
93 legitimate peer review process or follow other editorial best practices [34,35]. Today, one of the most
94 pressing concerns is the emergence of “paper mills” that sell co-authorships in real, or sometimes
95 machine-written, articles that authors can add to their CVs [36,37]. These specific concerns and the
96 resulting debates have led to multiple responses from the academic community, including greater calls
97 for research assessment reform [38], close scrutiny of the peer review system [39], and efforts towards
98 greater openness and transparency [40].

99 One place to enact such changes in research assessment is in review, promotion, and tenure
100 (RPT) processes, which often purport to reward many aspects of academic work but are known to place
101 emphasis on the number of publications [41] and the conflated concepts of prestige, quality, and impact
102 [42]. Proposed alternatives include the use of narrative CVs (i.e., allow those being assessed to describe
103 their career trajectory) [43], development of values-based indicators [44], and other assessment
104 frameworks that place emphasis on the quality over quantity of research outputs [45].

105 Generally, calls for research assessment reform have focused on pushing back on the simplistic
106 use of citation-based metrics, especially the Journal Impact Factor (JIF) [38,46]. While there is broad
107 consensus on the limitations and adverse effects of the JIF [47], its use for research assessment remains
108 widespread [28], in part because of the labour of assessing the quality of a growing number of
109 publications. Eve and Priego [48] argue that relying on these indicators is driven by a need to conserve
110 reading labour: the metrics let scholars decide what, in the vast body of literature, is worth reading, and
111 who among their peers is worth rewarding.

112 Peer review is another way in which the scholarly community has traditionally delineated
113 between problematic and reliable or “authoritative” scholarship [49]. Yet, like journal metrics, the
114 effectiveness of peer review itself has been subject to debates in recent years. These debates largely
115 centre on the (in)effectiveness and (in)appropriateness of peer review for weeding out problematic
116 research, but also include other considerations such as biases in the review system and their impact on
117 the diversity of the scholarly record; the burden of peer review on already strained academics; and the
118 lack of transparency involved [39,50–52].

119 Ongoing discussions about the role of OS in scholarly communication have brought another
120 layer of complexity to these debates about research integrity, impact, and assessment. Proponents of OS
121 argue that practices such as sharing research data and protocols or publishing open peer review reports
122 can bring transparency to the research and publication process and, in turn, improve the integrity of the
123 scholarly record [53], shift the scholarly community’s reward system toward valuing a more diverse
124 range of research outputs [54], or more broadly help to realign incentives as part of the push for research
125 assessment reform [55]. Advocates also see OS as a mechanism for making scholarly communication
126 more equitable and inclusive, as openness can allow less well-resourced scholars to access and, for some
127 forms of OS, contribute to research knowledge [56,57]. Yet others have raised concerns that OS may
128 further exacerbate existing problems in academia. For example, the high cost of article processing
129 charges required to publish OA in some journals could compound existing inequities in whose research
130 is published and rewarded [58]. Moreover, some fear that the growing use of un-peer-reviewed preprints
131 in scholarly communication, as was seen during the COVID-19 pandemic, could contribute to the spread
132 of flawed science, misinformation, and even conspiracy theories [59,60].

133 In sum, in reporting on research, journalists must navigate a contentious and rapidly evolving
134 scholarly communication landscape and an ongoing questioning of how research should be vetted,
135 valued, and rewarded. Due to their close relationships with scientists, it is likely that these challenging

136 debates influence how journalists think about and cover research; yet the nature of this influence is not
137 yet well understood. To address this important gap, we interviewed 19 health and science journalists
138 about their reporting practices and perceptions of research. Our results provide some of the first
139 evidence into how journalists have internalized key controversies in scholarly communication and how
140 this internalization shapes ways in which they report on research.

141 **Methods**

142 Guided by a constructivist paradigm, we conducted an interview study using qualitative
143 description [61], meaning that we aimed to gather data that describe the “why, how, and what questions
144 about human behavior, motives, views, and barriers” [62]. We selected this methodology as it is well
145 suited for use when interviewing individuals with direct experience of the studied phenomenon.

146 This study is a component of a larger research project in which we conducted interviews with
147 journalists and scientists. Given our research aim, this current investigation focuses only on the
148 journalists’ interviews. For further details of the larger project see Fleerackers et al. [63] and Moorhead
149 et al. [12]. The Simon Fraser University Research Ethics Board (# 30000244) and the San Francisco
150 State Institutional Review Board (#2021175) exempted the project from further review.

151 **Sample**

152 Eligible participants for this study worked for one of seven news outlets that included a mixture
153 of traditional, legacy news organizations (i.e., *The Guardian*, *New York Times*); historically print-only
154 science magazines (*Popular Science*, *Wired*); digital-native health sites (*News Medical*, *MedPage*
155 *Today*); and a science blog (*IFLScience*). We selected these news outlets based on their focus on science
156 and health news and frequent coverage of academic research. Their diversity (in formats, publishing
157 models, audiences) was also desirable because it was more representative of today’s digital media
158 ecosystem than a sample of traditional, legacy news outlets. Journalists from these outlets were eligible
159 to participate if they had published a story between March 1 and April 30, 2021, that included a mention

160 of research. Mentions of research were identified through the outlet's RSS feed or via the Twitter
161 timeline of the official account that posted a link to every story. We have made the scripts used for this
162 process openly available [64].

163 **Data Collection**

164 Between July and November 2021, a research assistant with experience in journalism emailed
165 eligible journalists to participate using publicly available email addresses. Nineteen journalists were
166 interviewed (see Fleerackers et al. [63] for participant characteristics). Journalists consented to
167 participate in the study via a consent form sent before the interviews were conducted.

168 The research assistant conducted and recorded semi-structured interviews with the journalists via
169 Zoom. In the interviews, participants were asked to describe their professional experience reporting on
170 research, including how they engage with scientists. The interview guide is available online [65].
171 Interviews were on average 35 minutes (range: 10-47 minutes). A third-party transcriptions service
172 transcribed all transcripts, which were then de-identified by LLM prior to analysis.

173 **Data Analysis**

174 Analysis of the data began with AF identifying and highlighting sections of the transcripts
175 broadly applicable to the participants' descriptions of their engagement with scientific debates and
176 practices (e.g., searching for studies via academic databases, evaluating research quality based on
177 methodological criteria, placing trust in peer review, valuing citation counts or journal reputation,
178 supporting the OS, etc.). All authors were provided access to the complete, highlighted transcripts and
179 tasked with familiarizing themselves with the overall content and conducting open coding of elements
180 that might relate to journalists' understanding and adoption of scholarly debates and norms. The authors
181 then met virtually to discuss and co-create a working codebook, which was subsequently refined by AF
182 after additional readings of the transcripts to include draft definitions and examples of codes (i.e.,
183 codebook thematic analysis) [66]. The authors then independently applied the codebook to the

184 transcripts, while staying open to the identification of additional codes, and again met to discuss areas
185 requiring revision. Informed by these conversations, familiarity with the data, and literature on
186 journalism and scholarly communication, AF iteratively refined and applied the newly organized codes
187 to transcripts, and, eventually, solidified the codebook.

188 To explore potential patterns in how different types of journalists understood academic debates
189 and how this affected their work, AF did a final round of coding using the qualitative analysis software
190 NVivo 12 [67], which allows researchers to easily assess whether codes and themes are expressed by all
191 participants (i.e., cases) or by only a subset with particular demographic characteristics via its crosstabs
192 query functionality. Examining potential differences among types of journalists was important as some
193 of the participants had professional training or education in science (and thus would be theoretically
194 more likely to be aware of controversies in academia), while others did not. Similarly, some worked as
195 specialized science journalists at science-focused outlets, whereas others reported on other beats (e.g.,
196 lifestyle, culture) or worked for other types of outlets (e.g., general news outlets). The specialized
197 journalists could potentially be more sensitized to scholarly debates and norms than those with less
198 experience reading academic research or interacting with scientists. While our qualitative design did not
199 allow us to quantitatively compare different groups of journalists, we assessed whether evidence of each
200 theme was present among each type of journalist. Specifically, we looked for the presence of each theme
201 among journalists of different educational backgrounds (i.e., in journalism, science, both, or some other
202 field), levels of education (i.e., bachelor's, master's, doctoral, unknown), years of experience (i.e., 0–4,
203 5–9, 10+), roles (i.e., staff reporter, freelancer, staff editor), and beats (i.e., science/health vs other). We
204 also assessed whether themes were expressed by journalists working at outlets of different types (i.e.,
205 traditional/legacy journalism vs alternative/peripheral media)[68] and different topic specializations (i.e.,
206 health/science vs other). The final themes (described in the Results and Discussion section) were
207 expressed by journalists within each of these subgroups.

208 **Reflexivity**

209 Our research team included individuals with a variety of backgrounds and experiences as
210 researchers (all authors), journalists (AF and LLM), and communication professionals (AF and MR)
211 who have worked in North American contexts. JPA’s research focuses on scholarly communication,
212 while LAM studies the prevalence of irresponsible research practices by scientists. Additionally, all
213 members of the research team shared a background and interest in OS and the responsible use of
214 research metrics. Taken together, the research team’s interests and expertise likely influenced the study
215 aims, analysis, and conclusions.

216 **Results and Discussion**

217 Our results suggest that journalists are generally aware of, and influenced by, debates about
218 issues such as research integrity, impact metrics, and OS that are taking place within academia. Yet,
219 journalists vary widely in terms of how closely they are enmeshed with these debates, with some
220 presenting a highly critical and nuanced understanding and others presenting a more limited awareness.
221 These different levels of awareness contribute to different approaches to reporting on research. We
222 report these varied perspectives and practices below and discuss their implications for the nature of
223 science media coverage. To provide context for our findings we provide direct quotes from participants
224 across our sample. Participants are identified by their participant number (e.g., J11 is journalist
225 participant 11).

226 **Critical Awareness of Academic Debates**

227 Interviews with journalists revealed that some had a deep awareness of ongoing debates and
228 discourses taking place within the scholarly community—an awareness that sometimes influenced how
229 they selected, verified, and communicated research. For example, journalists expressed a nuanced
230 understanding of the limitations of peer review, including its slow, potentially biased, and often
231 imperfect effectiveness as a quality control mechanism [39,69]. Others referenced related challenges to

232 research integrity, such as the ongoing replication crisis, the rise of predatory journals, the pressure to
233 publish and its implications for research quality, and the problematic nature of publication bias. J11, for
234 instance, noted that “there are certain—what’s the word—certain pressures, you know, to sort of publish
235 or perish and that people might be kind of cranking out a lot of articles.” This awareness of ongoing
236 challenges to the integrity of science led some journalists to report findings with additional scrutiny.
237 This was the case for J1, for example, whose knowledge of the replication crisis made them skeptical of
238 using older research if “there’s no follow-up” or newer studies that have come to similar conclusions.

239 Perhaps because of their awareness of research integrity issues, journalists described relying on
240 scientific methods for ensuring the research they reported was accurate, unbiased, and trustworthy. This
241 included, above all, a consideration of the study design and methodology. Although several journalists
242 noted that they lacked the expertise to effectively verify complex statistical analyses [70], they still
243 attempted to scrutinize the quality of the research before deciding to report on it, something that is
244 notoriously difficult to define and assess, even from within the scientific community [71]. Common
245 strategies included critically reading the paper and investigating the nature and size of the sample;
246 human subjects were valued above mice, and larger samples were generally seen as more trustworthy
247 than smaller ones. (One journalist, however, noted that small samples are appropriate in qualitative
248 studies, demonstrating a more nuanced understanding of research methods and study design.) Meta-
249 analyses and randomized controlled trials (RCTs) were preferred over other types of studies, which
250 aligns with how researchers conceptualize the hierarchy of available evidence [72,73]. Journalists
251 looked for causality, in ways similar to scientists, asking questions such as, “Is there an implicit bias in
252 the study? Are the conclusions valid? Is it really a causation, for example, or just a correlation?” [J12]
253 and noting whether “their methodologies leave this open to be, like, a correlation, not necessarily a
254 causation” [J15]. Finally, some journalists saw research as more credible when researchers noted study
255 limitations and did not have any clear conflicts of interest, aligning with the consensus building in the

256 scientific community that transparent reporting is an indicator of research integrity [74]. A few
257 journalists went even further, running their own statistical tests on publicly available datasets to provide
258 new insights. These journalists made comments such as, “I was very much playing the scientist, almost,
259 in that I was the one writing, ‘What does the data mean?’” [J2].

260 Journalists’ critical understanding of academic debates extended beyond issues of research
261 quality. For example, some journalists noted the increasing need for universities to establish legitimacy
262 and gain public support through self-interested science public relations efforts, echoing similar findings
263 to those described by Weingart [11]. This was reflected in comments such as “[Research papers] come
264 to me either directly if I’ve worked with them before or through their press release offices, right, which
265 are pumping out research all the time in order to garner interest” [J4]. Others, such as J12, expressed
266 awareness of the importance of establishing priority as a scientist and avoiding getting “scooped.” This
267 knowledge, in turn, informed how and when they reported on scientists’ research:

268 ...you have to cover [a] preprint as soon as possible...Give the researchers that put the preprint
269 also another, how to say it, another stamp of—they were the first—that their research was the
270 first, because sometimes, that can be problematic in scientific circles [J12].

271 Even more common were discussions about the public’s right to access research—a core pillar of
272 the OS and OA movements that have been gaining momentum in academia over the past two decades
273 [57]. These reflections on the public’s right to research knowledge were often grounded in journalists’
274 own frustrations in accessing the literature, as evidenced by J19, who stated that “it’s so frustrating when
275 you finally find the paper that you want to read and it’s behind a paywall, particularly when it’s publicly
276 funded research, you know?”

277 Yet journalists also discussed OA in other contexts, such as when reflecting on the rise of
278 preprints during the COVID-19 pandemic. Journalists expressed an awareness of the benefits that
279 scientists find in preprints, as both a rapid-sharing mechanism that avoids the slow peer review and

280 publication process, and as a way to circumvent paywalls from costly subscription journals [75]. As J16
281 explained,

282 [Preprints are] the way that scientists talk quickly to each other, and especially as people realize
283 that they don't have easy access to the big journals because they cost a lot of money and they're
284 behind paywalls, that this becomes much more of a way for scientists to talk to each other and to
285 a potential audience for that work.

286 **Limits in understanding of academic debates**

287 Journalists' in-depth understanding of academic debates was not universal, however. For
288 example, alongside journalists who were skeptical of peer review were journalists who saw it as the
289 "gold standard" [J13] to guarantee that findings were trustworthy and credible enough to report on.
290 These journalists made comments such as, "with the peer reviewed piece, you're really saying 'This is a
291 discovery or something that is fairly well-vetted and legitimate'" [J18]. Scholars have previously noted
292 that journalists use peer review as a stamp of approval, one which moves the findings from uncertain
293 evidence to confirmed facts [6,76,77]. This view of peer review aligns with that of many researchers
294 [78] despite criticisms that peer review is not a reliable quality control system and can, at times,
295 introduce biases [39,50].

296 Similarly, while some journalists were aware of the pressures researchers faced to demonstrate
297 "impact," others uncritically accepted and relied on measures of impact used by many scholars.
298 Specifically, journalists described selecting studies to report based on indicators such as the number of
299 citations an article receives, the impact factor of the journal it is published in, and the reputation of the
300 journal, the authors, and their institutions [29,79]. This reliance on proxies for research quality and
301 impact can be seen in comments such as "you can do stuff to verify how, the impact factor of a journal
302 or how legitimate the research is" [J9] and "that's why they're in *Science* and *Nature*, 'cause they're big

303 stories, they're important" [J5]. As J10 explained, over time, these indicators formed an internalized
304 framework that journalists could fall back on without having to critically scrutinize study findings:

305 We've got, like, a fairly good understanding of we know the journals that you almost don't have
306 to question too much, you know, like, the *Nature* journals, *Science*, *PLOS ONE*, all the *PLOS*
307 ones, you kind of realize, like, these are fairly well-respected, so you don't have to question them
308 too much.

309 The focus on reputational assessment strategies aligns with findings of Badenschier and Wormer
310 [80] and Rosen et al. [81], who similarly identified "scientific relevance" as a value shaping science
311 journalists' selection decisions. Deferring decisions about the impact or quality of scientific outputs to
312 recognized scientific community mechanisms potentially saves time for journalists, but our findings
313 reveal how doing so can enable problematic aspects of academia to seep into journalism, such as an
314 overreliance on citation-based metrics of "impact" and journal reputation [48]. Citation indicators such
315 as the JIF are known to be poor measures of the quality of individual articles and to be biased against
316 journals in the social sciences and humanities, as well as those from the Global South [47,82]. The use
317 of these metrics by journalists could serve to further perpetuate their problematic use within academia.

318 Similarly, while some journalists were aware that scientists faced pressures to promote their
319 work, this did not translate to a critical relationship with press officers or the scientists whose work they
320 promoted. Instead, journalists looked to journal and university press officers to understand the research,
321 as reflected in comments such as:

322 I couldn't do my job without the public information officers. They're great, and especially for
323 some of the studies that are written in a language that even I find quite difficult to access, like
324 nothing is better than a press release to just get your head straight about what the top-line
325 findings of something are. [J18]

326 Similarly, none of the journalists in our sample mentioned the importance of maintaining
327 independence from the scientists they interviewed, even though independence from sources is one of
328 journalism’s core values [83] and a foundational ethical principle of science journalism [84]. Instead,
329 journalists described their relationships to scientists as collaborative and trusting, as reflected in
330 statements such as, “Obviously, I have my own sources, and if I have a source who’s in that topic area, I
331 would reach out to them,” [J17] and, “I have sources that I rely on and that I think are trustworthy, and I
332 go to them” [J7]. Journalists expected scientists to act as unbiased experts on the topic at hand, even
333 while acknowledging their fallibility. As J7 noted, incorporating expert opinions “gives [the story]
334 credibility that makes me feel better, even though, yes, they sometimes are not all that accurate” [J7].

335 As has been noted in previous research [6,63], journalists leaned heavily on these trusted sources
336 to critique and vet other researchers’ work. Yet, journalists relied on scientists for more fundamental
337 aspects of their reporting as well. Many asked experts to translate the research—to “give more insight
338 and clear explanation to the article that we could provide by ourselves” [J1]. This was especially
339 important for journalists without a background in science, such as J11:

340 One thing is that, again, often kind of coming in as a liberal arts backgrounded person with not a
341 huge understanding of something like computational fluid dynamics, that I would hope that they
342 are a resource I can trust, you know, and, again, that gets into a tricky thing, because, you know,
343 if I can’t tell that they’re wrong, you know, who’s going to tell me they’re wrong?

344 Journalists also used scientists when seeking out research to cover or incorporate in their stories,
345 “relying on the expertise of people who research in that area to point me towards the like, external
346 literature to begin with” [J14]. On a practical level, journalists also frequently used scientists to get
347 access to (paywalled) research papers [9,85]. This was true even of participants working at major
348 publications, such as the staff reporter at *The Guardian* who reported that, “A lot of the time, it’s really
349 hard to find a PDF of the paper, and, like, scientists are brilliant. If you email them, they send you a PDF

350 of the paper” [J19]. In this sense, scientists not only acted as collaborators in journalists’ work [12] but
351 also as gatekeepers and agenda setters. Their actions and input helped shape what research got coverage,
352 as well as how it was contextualized and framed [86]. Scientists, scientific institutions, and scientific
353 journals were assumed to stand by the research findings they communicated with conviction.

354 Science journalists’ overly reliant relationships on expert sources have been discussed elsewhere
355 [84,87] and align with the narrower definitions of scientization used in previous research—i.e., the
356 increasing influence of scientific and expert sources on journalists’ work [3,88]. Our findings extend this
357 previous research by providing a view into how and why journalists work with particular scientists and
358 how they come to negotiate this intersection of seemingly disparate professions.

359 **Limitations**

360 These findings must be considered in light of several limitations. First, the journalists we
361 interviewed responded to the recruitment email, which suggests they likely had an existing interest in
362 science relations and may thus have been more enmeshed in scholarly communication debates than
363 others. They also represented a specific subset of journalists—those who reported on research at least
364 occasionally, produced text-based stories, worked for online (rather than broadcast) media outlets, wrote
365 in English, and were based in the Global North. The participants were also interviewed during the
366 second year of the COVID-19 pandemic, when public interest in science was high [89] and concerns
367 about research integrity were growing [90]. The practices and understanding of academic debates we
368 identified may thus differ from those we might find among journalists working in other geographic,
369 linguistic, professional, and temporal contexts. Relatedly, the qualitative nature of the study design
370 means that it was not possible to systematically assess differences among journalists based on
371 publication outlets, reporting interests, or other characteristics. Future research could test our framework
372 with a larger sample of science journalists and a study design that would allow for comparisons across
373 participant contexts and characteristics.

374

Conclusion

375

376

377

378

379

380

381

382

383

384

In this study, we used in-depth interviews with journalists who report on science to further explore and understand the consequences of recent debates in scholarly communication and the close and codependent relationships that can develop between journalists and scientists that have been described by Franzen et al. [5], Weingart [11], Moorhead et al. [12], and others. In doing so, our analysis revealed how evolving academic debates not only influence how journalists perceive research studies (e.g., as valuable, impactful, trustworthy, or high-quality), they also shape their practices for reporting on them. Our findings present some of the first evidence of the impacts of the “scientization” of journalists described by MacGregor et al. [3], contributing to scholarly understanding of the interrelationships between science and journalism and shedding light on journalistic practices with important practical implications.

385

386

387

388

389

390

391

In some instances, journalists possessed an in-depth, critical understanding of academic debates about research integrity, which appeared to encourage a more critical approach to communicating science that could benefit their audiences. For example, some journalists expressed a deep awareness of the limitations of peer review and approached research studies with a skeptical eye. They decided which studies to report on by adopting practices used by many scholars, such as considering the study design and methodology and, in some cases, doing their own independent research (e.g., assessing the existing literature, collecting and analyzing their own data, and creating meaningful data visualizations).

392

393

394

395

396

397

At other times, however, journalists expressed a more superficial understanding of key challenges facing academia, which sometimes translated to problematic practices for reporting on research. For instance, some journalists described relying on academic citation metrics or markers of prestige as proxies for research quality—both practices that are themselves critiqued within academia [47]. None of the journalists we interviewed appeared to be concerned about maintaining independence from the scientists they were covering in their work, and most also trusted the information they received

398 from university and journal press officers. This uncritical reliance on scientists and press officers was
399 true even among journalists who acknowledged the potential fallibility of these sources and described
400 the pressures facing scientists and scientific institutions to demonstrate the societal “impact” of their
401 work. That is, at times, journalists’ reliance on scientific experts appeared to compromise their ability to
402 serve the public interest and retain independence and autonomy from their sources—two commonly
403 cited journalistic values [83,91].

404 Finally, journalists—as seen in the quotation “Who’s going to tell me they’re wrong?”—often
405 recognized their limits in understanding and ability to vet research. Yet, their efforts to verify or
406 triangulate research sometimes moved them closer to academia’s controversies and insular practices
407 (e.g., press officers acting as knowledge brokers, scholars hesitant to speak on the work of peers, early-
408 stage researchers desiring press coverage for their projects). Moving forward, there is a need to explore
409 how journalists might better understand and document research integrity independently, without an
410 overreliance on academia’s potentially limited and biased networks. Relatedly, our results suggest that
411 advocates of OS have allies in science journalism, as journalists, too, appear to believe that research
412 knowledge should be public knowledge. It is unclear, however, whether journalists align themselves
413 with other OS goals, such as advancing transparency and improving research integrity, or make use of
414 the increasing number of datasets, protocols, and other research outputs that are openly available [21].
415 As such, researchers may wish to explore how these open research outputs shape journalists’ practices
416 for selecting, verifying, and communicating research to the public, as well as what new or additional
417 tools and resources could be developed to support their work.

418 **Acknowledgements**

419 We would like to acknowledge Mr. Asura Enkhbayar for his support in collecting the news
420 stories which were used to identify potential participants and Ms. Kaylee Fagan Williams for her
421 assistance in conducting the semi-structured interviews.
